THE WATER FLOSSER: YOUR TOOL FOR OPTIMAL HEALTH
DISCLOSURE STATEMENT

• The content for this self-study course was written by Carol A. Jahn, RDH, MS, an employee of Water Pik, Inc., a subsidiary of Church & Dwight Co., Inc.
• This course was designed, developed, and produced by Water Pik, Inc.
• Water Pik, Inc manufactures and distributes products addressed in this course.

COURSE OBJECTIVE

To provide the learner with a comprehensive scientific review of the efficacy and safety of the Water Flosser, which will enable dental professionals to recommend, educate, and instruct individuals regarding the use of a Water Flosser.

LEARNING OUTCOMES

• List the oral health benefits demonstrated by the Water Flosser
• Discuss the effect the Water Flosser has on plaque biofilm and inflammation
• Compare the use of the Water Flosser to string floss
• Evaluate solutions/agents for use in a Water Flosser
• Understand the benefits of a Water Flosser for individuals with gingivitis, periodontitis, implants, diabetes, orthodontics
• Instruct individuals in the use of the Water Flosser

INTRODUCTION

The Water Flosser, like many successful products, was born from both failure and persistence. Dr. Gerald Moyer, a Fort Collins, Colorado, dentist, wanted a water irrigation device to help his patients with periodontal disease. He collaborated with his friend and patient, John Mattingly, a hydraulics engineer at Colorado State University. The two worked together on the device every evening. It was not until their 146th attempt that they developed the precise engineering needed for the product.

The first Water Flossers were handmade by John Mattingly (Figure 1). Dr. Moyer gave one of these devices to a patient who had periodontal problems. The patient used it religiously for 6 months and was so happy with the improvements in his mouth that he invested in the company and later went on to be its first president. He was so confident in the Water Flosser that he convinced more than 20 other Fort Collins business leaders, many of whom were dentists, to invest in the product. The first place these original board members chose to sell the product was a dental convention.

More than 50 years since its inception, the Water Flosser is backed by over 70 research studies that consistently demonstrate its safety and effectiveness. With today’s focus on scientific evidence as the benchmark, long-ago anecdotal stories and personal case reports on the water flosser have been exposed as unreliable opinions. Systematic reviews and randomized clinical trials (RCT) are the gold standard in clinical research (Figure 2). RCTs provide built-in safeguards such as blinding and randomization to prevent investigator or confirmation bias. A systematic review focuses on a single research question and reviews multiple RCTs to determine which products, therapies, and other interventions provide the best outcomes. In comparison, personal case reports are considered weak evidence because there is no verification of the outcome via a control group, blinding, or other safeguards.

More dental professionals than ever recommend the Water Flosser to people who will not floss, have orthodontic appliances, implants, crowns, bridges, and gingivitis, or are in periodontal maintenance. Studies support the use of the Water Flosser for these clinical indications. The Water Flosser has been clinically proven to reduce numerous clinical parameters including calculus, plaque/biofilm, gingivitis, bleeding, periodontal pathogens, probing depth, and inflammatory mediators.

HOW IT WORKS: ACTION AND DEPTH OF DELIVERY

The critical action of the Water Flosser is its unique combination of pulsation and pressure. They create a compression and decompression phase that can remove plaque biofilm and disrupt bacteria. Compared to a steady stream, a pulsating device has
been shown to be three times as effective at removing debris. Conventional wisdom says that water cannot remove plaque and that mechanical action is required. Pulsating water under pressure is different from simple swishing because the combination of pulsation and pressure produces sheer hydraulic forces that are capable of removing plaque biofilm.

Cobb et al. and Drisko et al. both found that water flossing capable of removing plaque biofilm. Pulsation and pressure produces sheer hydraulic forces that are mechanical action is required. Pulsating water under pressure has been shown to reach up to 68% in deep pockets.

Click here to see a video of a water flosser removing plaque biofilm.

Another outcome from pulsation and pressure is hydrokinetic activity, which provides for subgingival penetration into the sulcus or pocket. Studies evaluating a standard jet tip (Figure 3) have found that it allows the solution to penetrate, on average, approximately 50% of the depth of the pocket. Investigators also found that depth of penetration was better with the tip placed at a 90° angle to the tooth versus a 45° angle (Table 1). Others have looked at disruption of bacteria. Cobb et al. and Drisko et al. both found that water flossing with a standard jet tip can reduce periodontal pathogens up to 6 millimeters.

The use of a soft, rubber, site-specific tip (Figure 4) provides localized delivery to an individual site such as a deep pocket, furcation, implant, crown, and bridge. This type of tip should be used as an adjunct to a jet tip, implant tip, or orthodontic tip. It has been demonstrated via a clinical trial to deliver a solution into the pocket up to 90% of its depth in pockets 6 mm or less. For pockets 7 mm or greater, depth of penetration is 64%.

Click here to view the depth of penetration from a site specific tip.

Evidence indicates that the Water Flosser has the greatest potential of any self-care device for subgingival access into the periodontal pocket (Table 2). Studies documenting subgingival access in vivo for tooth brushing and flossing are limited. Conventional wisdom rather than scientific evidence says that tooth brushing typically reaches 1–2 millimeters and traditional dental floss up to 3 millimeters. The ability of a sonic toothbrush to have an effect on bacteria subgingivally has been tested only in the laboratory setting and has not been proven definitively in vivo. Others have found that depth of penetration was better with the tip placed at a 90° angle to the tooth versus a 45° angle.

WHAT IT DOES: REDUCTION OF CLINICAL PARAMETERS

One of the first clinical studies on water flossing was published in the Journal of Periodontology in 1969. Since that time more than 70 additional studies have been conducted at university- and research-based facilities by experienced investigators and published in peer-reviewed journals. These studies have evaluated clinical parameters such as calculus, plaque/biofilm, gingivitis, bleeding, periodontal pathogens, probing depth, and inflammatory cytokines.

Calculus. One of the earliest studies on water flossing looked at calculus reduction and found that adding a Water Flosser to tooth brushing reduced calculus by 50%. Others have found similar findings. Water flosser devices that promote the benefits of magnetic polarity have been endorsed as tools for enhancing calculus reduction. In two separate clinical trials, a unit with magnetic polarity was compared to a unit of the same brand minus the magnet. The unit with the magnet was shown, via a novel index that combined calculus and plaque, to provide a greater calculus reduction on lower anterior teeth. However, this enhanced calculus reduction did not result in greater improvements in oral health because gingivitis reductions between the magnetized and non-magnetized unit were similar. In addition,
the index used to measure plaque and calculus was new and had not, and has not yet, been validated.

**Plaque biofilm.** For many years, it was widely believed that water flossing could not remove plaque biofilm. Studies from the 1990s conducted on periodontal maintenance patients often reported minimal or no increased reduction of supragingival plaque biofilm with water flossing, yet significant improvements in bleeding or gingivitis were shown.\(^{15, 20-25}\) Several investigators hypothesized that the effect might be due to changes in the subgingival biofilm composition including an alteration in key pathogens.\(^{20, 22, 24, 25}\)

![Removal of Plaque Biofilm with Classic Jet Tip](image1.png)

![Removal of Plaque Biofilm with Classic Jet Tip](image2.png)

More recent studies resulted in different findings. Eleven studies conducted since 2000 have reported positive findings regarding water flossing and plaque biofilm removal.\(^{32-35}\) A study conducted at the University of Southern California Center for Biofilms evaluated the effect of shear hydraulic forces from water flossing on plaque biofilm using scanning electron microscopy (SEM).\(^1\) Eight teeth were extracted from a patient with advanced periodontal disease. Pretreatment SEM images of the teeth found they were colonized by a luxuriant biofilm appearing several micrometers thick (Figure 5). The teeth were water flossed for 3 seconds at a medium pressure (70 psi) setting. Post-SEM images found that water flossing removed up to 99.9% of plaque biofilm\(^5\) (Figure 6). The researchers concluded that the shear hydraulic forces produced by a water flosser with 1,200 pulsations per minute at medium pressure can significantly remove biofilm from tooth surfaces.\(^1\)

The plaque biofilm removing capabilities of the Water Flosser were further evaluated in a single-use study. Seventy adults abstained from all oral hygiene for 23–25 hours. The subjects rinsed with a red disclosing solution then used a manual toothbrush and a Water Flosser or a manual toothbrush and dental floss. Standard brushing and flossing instructions were provided as were directions for using the Water Flosser. The investigators found that the Water Flosser group removed 74% of whole mouth plaque compared to 56% for string floss, making the Water Flosser 29% more effective.\(^5\) The Water Flosser also removed nearly 82% of approximal plaque compared to 63% for string floss\(^6\) (Figure 7). These findings are supported by Sharma et al., who found the Water Flosser removed 75% of whole mouth plaque and 83% of approximal plaque.\(^32\)

![Figure 5: Before treatment with the water flosser, Gorur et al.]()![Figure 6: Tooth surface after a 3-second treatment with the Water Flosser, Gorur et al.]()

**Gingivitis and bleeding.** While bacterial plaque biofilm is an essential precursor to gingivitis and periodontal disease, today it is widely established that each individual may respond differently to plaque biofilm, leading to broad differences in the extent and severity of disease among patients. It has been demonstrated that some people are over-responders to plaque biofilm, while others may have diffuse plaque and never progress beyond gingivitis.\(^36\) Because of this, reduction in bleeding is viewed as a more significant marker of health than plaque biofilm reduction.

Several studies have shown that the Water Flosser is extremely effective in reducing gingivitis and bleeding.\(^15-17, 20-29, 30-33, 35, 37-43\) In a University of Nebraska study, the Water Flosser was paired with a manual or a power toothbrush, and both were compared to traditional manual brushing and flossing to see which routine was the most effective. Regardless of toothbrush type, the addition of a Water Flosser, once daily with plain water, to a manual or a power brushing routine was a more effective alternative to string floss for the reduction of bleeding, gingivitis, and plaque. Notably, the Water Flosser was up to 93% better at reducing bleeding and up to 52% better at reducing gingivitis over manual flossing. Significant improvements in oral health occurred regardless of toothbrush type, so it is likely that many patients currently using a power toothbrush may get further improvements in oral health by the addition of a Water Flosser.\(^26\) Likewise, Goyal et al. found that people who used a power toothbrush and Water Flosser had significantly better bleeding and gingivitis reductions than those who used either a power (70%, 48% respectively) or manual toothbrush (159%, 134% respectively).\(^33\)

**Infection and inflammation.** The Water Flosser has been shown to reduce the pathogens responsible for initiation of the periodontal infection,\(^1, 8, 21, 23, 37, 43\) as well as the inflammatory mediators responsible for attachment and bone loss.\(^34, 37\) Cobb et al. and Drisko et al. demonstrated that a Water Flosser with water reduced bacteria up to 6 millimeters.\(^13\) Likewise, Chaves et al.
found the Water Flosser with either water or diluted chlorhexidine (CHX) reduced subgingival pathogens. In comparison, they found rinsing with full-strength CHX did not achieve the same results.22

The site-specific delivery tip also has been shown to be effective at reducing subgingival pathogens.37, 38 Jolkovsky et al. and Fine et al. used the site-specific tip to deliver an antimicrobial agent and found reduced inflammation and a decrease in pathogens.39

This tip is a good choice for individuals who have areas that are challenging to manage periodontally or have areas difficult to access such as a deep pocket, furcation, implant, crown, or bridge.

After years of speculation by researchers regarding the effect of water flossing on the immune system response, researchers at Baylor University evaluated how the Water Flosser affects the host inflammatory response.26 Cutler et al. looked at traditional periodontal outcomes plus measures of cytokines, also called inflammatory mediators.27 Cytokines were chosen because some, such as IL-1ß, have been implicated in stimulating osteoclasts to destroy alveolar bone.44,45 The investigators discovered that water flossing reduced crevicular cytokine levels, most notably IL-1ß, thus potentially inhibiting periodontal disease activity. It is important to note that measures of the cytokines were taken 8 hours after use of the Water Flosser so that any dilution effect would be eliminated.26 A University of Buffalo study also found that water flossing reduced the production of serum IL-1ß.27

Probing depth. Some investigators have looked at the effect of the Water Flosser on probing depth reduction. Most have demonstrated small yet statistically significant reductions generally ranging from 0.1 millimeters to 0.4 mm.16, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29

The clinical significance of this finding lends support to the safety of the Water Flosser as well as its potential for helping periodontal maintenance patients maintain stability.

WHO BENEFITS FROM USING A WATER FLOSSER

The Water Flosser has long been a mandatory device for people in orthodontic treatment25, 42 and periodontal maintenance.20, 27, 29, 42

More recently, the Water Flosser has emerged as one of the few self-care tools that has been tested on people with implants and found safe and effective for daily use.16, 43 However, the largest group to date that has been shown to benefit from a water flosser are those who cannot, will not, or simply do not floss.28,29

Orthodontic appliances present significant cleaning challenges for patients of any age. A study of 106 adolescents 11–17 years of age compared manual tooth brushing plus a Water Flosser with a tip designed specifically for orthodontic appliances (Figure 8) to two other groups: manual tooth brushing plus flossing via a floss threader versus manual tooth brushing alone. The results showed that the addition of the Water Flosser to tooth brushing reduced 3.76 times more plaque than flossing with a floss threader and 5.83 times more plaque than manual tooth brushing alone. The Water Flosser also provided a significantly better reduction in bleeding: 84.5% from baseline. This was 26% better than the results achieved with dental floss, and 53% better than brushing alone.22 (Figures 9, 10). These results are in line with a study on adult orthodontic patients that found, regardless of whether a manual or power toothbrush were used, adding a Water Flosser provided significantly better reductions in bleeding and inflammation.16

Click here to see the use of the orthodontic tip

Periodontal maintenance. Statistics indicate that nearly half of U.S. adults aged 30 and older have periodontitis.46 This fact suggests that helping people prevent and arrest periodontal disease is a top concern for most dental practices. The Water Flosser has a well-established body of evidence for improving oral health in periodontal maintenance patients.20, 27, 37, 42 A recent study by Genovesi et al. evaluated the difference between scaling and root planing (SRP) followed by the local delivery of minocycline or SRP followed by daily water flossing for 30 days. The results demonstrated that both treatments effectively reduced bleeding on probing and improved pocket depth and clinical attachment at 30 days46 (Figures 11, 12, 13). There were no statistical differences between the groups, thus showing that the Water Flosser is an effective alternative to subgingival antibiotics for periodontal maintenance patients over a 30-day period.42

Several 6-month studies were conducted during the 1990s on periodontal maintenance patients.20, 21, 22, 25 Findings from these studies consistently showed that the Water Flosser improved the oral health of this demographic. Notably, water flossing is extremely effective at reducing bleeding upon probing (BOP). Flemmig et al. found that water flossing reduced BOP by half over the 6-month time frame,47 and Newman et al. showed that those with the most BOP had the greatest reductions.20

In a different study, Flemmig et al. found that water flossing was
more effective than rinsing with 0.12% chlorhexidine at reducing BOP.\textsuperscript{25}

Diabetes has been shown to increase the risk for developing periodontal disease. A study at the University of Buffalo looked at how the Water Flosser benefited the periodontal health of people with diabetes. The results found that the addition of the Water Flosser to routine oral hygiene was more effective at reducing bleeding (64%) and gingival inflammation (41%) than routine oral hygiene alone. Plaque and gingivitis were also significantly reduced as well as the inflammatory mediators, IL-1ß and PGE\textsubscript{2}.\textsuperscript{27}

Implants have become the favored choice for single-tooth replacement. They are also vulnerable to both mucositis and peri-implantitis.\textsuperscript{27} Typically, traditional brushing and flossing have been the recommended self-care strategy. Recently, an observational study at the Academic Centre for Dentistry Amsterdam reported on 10 patients with progressive peri-implantitis. Flap surgery was undertaken, and in each case remnants of dental floss were found adhering to the roughened surface of the implant with peri-implantitis. The area was debrided, and nine of 10 patients had significant improvements.\textsuperscript{44} The investigators then did in vitro testing and exposed a pristine implant to cleaning with dental wax, leading the investigators to conclude that the use of dental floss may be a potential risk factor for peri-implantitis.\textsuperscript{48}

Two studies have been conducted with the Water Flosser and implants.\textsuperscript{51, 52} Magnuson et al. looked at the effectiveness of the Water Flosser in reducing bleeding around implants and compared it to string floss. After 30 days, the Water Flosser group was more than twice as effective at reducing in bleeding versus subjects using string floss. (\textbf{Figure 14}). No adverse effects were reported for either group.\textsuperscript{11} Likewise Felo et al. found that the Water Flosser with 0.06% chlorhexidine delivered via a site specific tip was 87% more effective in reducing bleeding around implants than rinsing with 0.12% chlorhexidine.\textsuperscript{53} A case-study by Salierno found that the Water Flosser was an effective component of the nonsurgical treatment of a case of mucositis.\textsuperscript{19}

\textbf{Click here to see the action of the water flosser around an implant}

Non-flossers. A common complaint of many dental professionals is that patients cannot, will not, or do not floss. Not surprisingly, a survey conducted for the American Academy of Periodontology found that more than a quarter of U.S. adults lie to their dentist about how often they floss. Over a third indicated they would rather do an unpleasant activity such as wash dishes, sit in traffic, or clean the toilet than use dental floss.\textsuperscript{54} A recent survey found that only 16% of people consistently floss every day. Twenty percent said they only flossed when something was stuck between teeth while 8% confessed to never flossing.\textsuperscript{55}

As much as traditional string floss is stressed and preferred by dental professionals, the evidence does not support its superiority in improving oral health.\textsuperscript{52-54} As systematic review by the prestigious Cochrane Collaboration\textsuperscript{5} looked at the benefits of string floss as an addition to tooth brushing for the management of periodontal diseases and dental caries in adults. Their findings indicated that there was some evidence that the addition of floss to tooth brushing reduced gingivitis and very weak, unreliable evidence that it enhanced plaque reduction. The investigators also found that no studies had been conducted that provide evidence that flossing reduces caries in adults.\textsuperscript{52} These findings are supported by Berchier et al.\textsuperscript{51} and Hujoel et al.\textsuperscript{53} Berchier et al. found that the addition of flossing to tooth brushing did not contribute to greater plaque and gingivitis reductions.\textsuperscript{51} In regard to caries, Hujoel et al. found no clinical trials evaluating the effectiveness of flossing in adults.\textsuperscript{54}
Both studies determined that dental professionals should determine on an individual basis whether high-quality flossing is an achievable goal.

Five studies have compared the Water Flosser to string floss, 28, 29, 30, 34, 41 and three studies 21, 22, 25 have compared the Water Flosser to powered devices that work with air and small amounts of water. In each study, the Water Flosser has been shown to be superior. 28-32, 34, 35, 41 In a 28-day study of 106 subjects, Rosema et al. 30 found that the Water Flosser was twice as effective as string floss at reducing bleeding at 2 weeks (Figure 15). This is supported by Magnuson et al., who also found water flossing twice as effective at reducing bleeding over a 30-day period. 41 In regard to plaque biofilm, when either the Water Flosser or string floss was added to manual tooth brushing, the Water Flosser was 29% more effective than string floss. 21

A study of 82 subjects over a 4-week period compared the Water Flosser to a device with air and a small amount of water. The results demonstrated that the Water Flosser was 80% more effective at reducing gingivitis and 30% more effective at reducing plaque than the first generation model of this product. 28 Similarly, Goyal et al., in a four-week study with 69 subjects, found that the Water Flosser was 54% better at reducing bleeding and 27% more effective at reducing plaque than the second generation model of this product 28 (Figures 16, 17, 18).

A study of 27 subjects compared the use of the Water Flosser to interdental brushes (IDB) over a two week time frame for plaque and bleeding on probing reduction. All subjects used a manual toothbrush. At the conclusion of the study the Water Flosser was 56% more effective than IDB at reducing BOP. For plaque, both groups had significant reductions from baseline. 28 A single-use plaque study also compared the Water Flosser and IDB and found the Water Flosser was 20% more effective than the IDB at removing plaque. 28

**THE SAFETY PROFILE OF THE WATER FLOSSER**

The Water Flosser is supported by more than 70 published scientific studies and over 5 decades of use by the public. Both countertop and cordless models have earned the ADA Seal of Acceptance. Despite this, skepticism about product safety and efficacy still persists. 37 Some dental professionals believe the product cannot be used at higher settings; other feel it increases probing depth or destroys the attachment.

A recent study by Goyal et al. evaluated the effect of the Water Flosser on gingival and epithelial tissue at multiple pressure settings; including the highest settings at 9 and 10. One hundred and five subjects were assigned to one of three groups; 1) manual brushing and Water Flossing, 2) manual brushing and flossing, and 3) manual brushing only. For the manual brushing and water flossing group, subjects increased the pressure setting on the Water Flosser over the course of the six week study (Figure 19). The primary outcome measured was clinical attachment levels (CAL) as assessed from the cementoenamel junction and probing pocket depth, PPD. At six-weeks, those in the Water Flosser group showed
an improvement in CAL and a reduction in PPD. These changes exceeded those in the manual brushing and flossing group and the manual brushing only group. All subjects received oral examinations at baseline, two-weeks, four-weeks, and six-weeks. All subjects were negative for oral lesions, trauma or any other abnormal findings at each visit. The investigators concluded that the Water Flosser is safe to use, and the results should alleviate concerns especially regarding pressure setting that the Water Flosser is detrimental oral health. The review looked at a wide range of studies. It covered topics such as trauma to soft tissue, penetration of bacteria into the sulcus, probing depth and bacteremia.2

Trauma to soft tissue was evaluated in a study at the University of Missouri Kansas City.7 Investigators examined untreated, chronic periodontal pockets immediately following irrigation with the Water Flosser. Examination of specimens under a scanning electron microscope showed no observable differences between the irrigated and nonirrigated specimens concerning the physical features and appearance of the epithelium. The investigators concluded that the Water Flosser does not injure soft tissue.7 This concurs with early work by Krajewski et al., who found less inflammation, better connective tissue organization, and an increased thickness in the keratin layer in individuals who used a Water Flosser twice daily compared to those who did not.28

Penetration and disruption of bacteria into the pocket have been studied by various researchers.5,7,8,22,23,27,30,43 Dr. Charles Cobb et al. evaluated the reduction of pathogens with a scanning electron microscope and found that areas treated with a Water Flosser had significantly less bacteria, up to 6 millimeters compared to areas that had not been water flossed.7 These results are supported by Dr Connie Drisko et al., who also found reduction of spirochetes up to 6 millimeters.4 Others also have found water flossing over a course of 3–6 months reduces periodontal bacteria.21,29,44 Collectively, these findings indicate that the potential for the Water Flosser to force bacteria into the pocket is highly unlikely.

Pocket depth has been evaluated in several studies, and none has found an increase in probing readings from the daily use of the water flosser.20,21,22,23,26,38,42,43 Cutler et al. found that the Water Flosser reduced probing depth by 0.4 mm in a 2-week time span.28 This is supported by Newman et al.,20 Flemmig et al.,21,26 and Chaves et al.,22 who found either small improvements or stable probing depths in periodontal maintenance patients who used the Water Flosser for a period of 6 months.

Bacteremia is a concern of dental professionals. The incidence of bacteremia from using a Water Flosser has been studied on numerous occasions.30-42 Post-water flossing, in people with gingivitis, the bacteremia rate was shown to be 7%,55 while in those with periodontitis showed 50%.42 For people with no history of periodontal disease and no evidence of gingivitis, Berger et al. found a 27% rate of bacteremia,16 whereas Tamimi et al. found no subjects developed bacteremia22 after using the device. This is similar to traditional tooth brushing and flossing at 20%-68% or mastication, up to 51%.25

WHAT SHOULD I TELL PATIENTS ABOUT USING THE WATER FLOSSER?

Compliance is enhanced when people enjoy using a product. Data indicate that people like and regularly use the Water Flosser.16,21,22,25,64 Hoover and Robinson noted that subjects felt that using the Water Flosser was a pleasant experience and that their mouths felt cleaner.27 Lainson et al. documented similar comments such as, “It stimulated the gums and made the teeth feel cleaner.”44

Mouthwash can be used in the Water Flosser to enhance compliance or for medicinal purposes. Almost any solution or mouth rinse can be used in a Water Flosser. When using something other than water, the unit must be flushed by partially filling the reservoir with water, removing the tip, and activating the system. If not, the life of the unit could be shortened.

Three different types of agents have a body of evidence to support their use. They are:

- Water
- Chlorhexidine
- Essential Oils

Water is a very effective agent. Some of the benefits of using water are:

- A true “natural” product
- No side effects
- Cost effective
- Readily available

Chlorhexidine (CHX) has frequently been evaluated in Water Flosser studies.16,21,24,25,39,43 One of the benefits of using CHX is better interproximal and subgingival penetration when compared to rinsing. Diluting CHX is acceptable for use in a Water Flosser. Dilutions (based on a 0.12% concentration) that have been shown to be effective via randomized clinical trials are:

- 0.02% = 5 parts water + 1 part CHX
- 0.04% = 3 parts water + 1 part CHX
- 0.06% = 1 part water + 1 part CHX

Essential oil mouthwash has also been studied as an irritant.21,38 An essential oil mouth rinse is readily available over the counter.
in name brand and generic forms. It is important to note that the effectiveness of essential oils is based on studies using it at full strength only. However, because water works, dilution is acceptable.

Instructions are an important component in water flossing. One of the best ways to give good instructions is to try the product. When giving instructions for the use of the Water Flosser, some general suggestions can make learning how to use it an easy and quick process.

- Read all manufacturer’s instructions prior to use.
- For practical purposes, don’t start the flow of water until the tip is in the mouth.
- Bend from the waist over the sink and hold arm up perpendicular to torso (Figure 19).
- Lips should be slightly closed to avoid splashing, but open enough to allow the water to flow freely from the mouth into the sink.
- Focus the eyes on the sink not the mirror
- Before removing the tip from the mouth, pause the flow of water or turn the unit off.
- For comfort, recommend using warm water or room temperature solutions.
- First time users should begin at the lowest pressure setting and increase as comfortable.

Click here to watch a short video on how to use the water flosser

WHICH MODEL AND TIP IS BEST FOR MY PATIENT?

When considering which type of model to recommend, lifestyle and personal preferences should be determining factors. The two basic types of models, countertop and cordless, have a pulsation rate and pressure range consistent with what is needed to achieve clinical outcomes. The ADA Council on Scientific Affairs has awarded the Waterpik® Water Flosser the Seal of Acceptance based on its findings that the product is safe and has shown efficacy for removing plaque along the gumline and between teeth and helping to prevent and reduce gingivitis, when used as directed. (Figure 20)

The Waterpik® Aquarius® Professional Water Flosser (Figure 21) is the top-of-the-line product in the Water Flosser category. It has a sleek design and features two water flossing modes: floss for the ultimate in interproximal cleaning and hydro pulse massage for enhanced gingival stimulation and circulation. The unit features an upgraded on/off water control on the handle to control the flow of water at the fingertip. The Aquarius® has a 1-minute timer and 30-second pacer for optimized cleaning of all areas of the mouth. The large reservoir provides 90 seconds of cleaning. It has 10 pressure settings and comes with seven tips.

The Waterpik® Whitening Professional Water Flosser (Figure 22) delivers precision whitening while patients reap the benefits of Water Flossing. The Whitening Water Flosser provides the same features as the Waterpik® Aquarius® along with whitening infuser technology in the handle for gentle stain removal. It has been shown to remove 25% more stain at 2-weeks than toothbrushing alone.°° (Figures 23 & 24) It comes with one 30 count bottle of whitening tablets.

The Waterpik® Sidekick® Water Flosser (Figure 25) features all the power of a countertop unit in a contemporary and compact design. It comes with a travel case and is small enough to fit into a purse or briefcase. It is ideal for travel coming with global voltage capability.

Waterpik® Sonic-Fusion® (Figure 26) is the newest addition to the Waterpik® family of oral health products. It combines the power of sonic toothbrushing with the proven efficacy of Water Flossing to deliver a complete clean in one step. Sonic-Fusion® has been shown to be up to twice as effective as manual brushing.
and flossing for reduce plaque, bleeding, and gingivitis.

The Waterpik® Cordless Advanced (Figure 27) features a new state of the art charging system. A microprocessor controls the charging system proving long battery life and recharging only takes four hours. LED indicator lights provide at-a-glance status for pressure and battery charge. The unit also has global voltage and comes with a tip storage case and travel bag. For those who like to water floss in the shower, the unit is waterproof. The Cordless Advanced has three pressure settings and comes with four tips. It is available in four designer color options. Five different types of tips are available to be used on the Waterpik® Water Flosser, allowing for a customized approach depending on individual patient needs (Figure 28). The standard jet tip is also called the Classic Jet Tip and it is for generalized cleaning. The Orthodontic Tip is ideal for those in orthodontic appliances. The Plaque Seeker® is a great choice for implant patients, and the Pik Pocket® Tip helps people access difficult to clean areas such as deep pockets, furcations, and around crowns and bridges.

Use the Classic Jet Tip, Plaque Seeker® Tip, Orthodontic Tip,
or Toothbrush Tip
- Begin in the molar area and follow a pattern throughout the mouth. This helps avoid missing areas.
- Place the tip between the teeth at a right, 90-degree angle to the long axis of the tooth at the interproximal space (Figure 29).
- After the unit has been turned on and water has begun pulsating, hold the tip in place at the interproximal area for 3 seconds. This allows adequate penetration of the solution into the gingival crevice or pocket.
- Move the tip around the mouth in a linear fashion following the gingival margin. Make sure that all areas are irrigated from both the buccal and lingual regions.
- The Orthodontic Tip can also be used around orthodontic brackets.
- With the Toothbrush Tip, brushing action should also be employed. Toothpaste may be used.

The Pik Pocket® Tip has been designed for low-pressure delivery. It is latex free. Because this tip is site-specific, individuals will need to know exactly where in the mouth it should be used. It is also best used with a countertop model.
- Turn the unit to the lowest pressure setting. If the user forgets, the pressure will still emit at 20 psi, though failure to do this may shorten the life of the unit (Figure 30).
- Gently place the tip just slightly below the gingival margin (Figure 31).
- Use a mirror to check that the tip is in the correct place.
- Briefly hold the tip in place before proceeding to another area.

**SUMMARY**

Since its introduction in 1962, the Water Flosser has been evaluated in numerous clinical trials that have demonstrated its safety and efficacy. It has been shown to benefit a wide variety of patients and clinical considerations including people with orthodontic appliances, implants, diabetes, in periodontal maintenance, and non-flossers. A wide array of units that can fit the lifestyle of anyone are available.
REFERENCES

1. Which statement is true regarding pulsation and pressure?
   a. It is less effective than a steady stream.
   b. It is similar to swishing.
   c. It doesn’t allow the solution to penetrate into pocket.
   d. It produces sheer hydraulic forces capable of removing plaque biofilm.

2. On average, the estimated depth of delivery into the sulcus using the jet tip at a 90 degree angle is:
   a. 10% of the depth of a pocket.
   b. 20% of the depth of a pocket.
   c. 50% of the depth of a pocket.
   d. 100% of the depth of a pocket.

3. Which statement is true regarding the water flosser and plaque biofilm removal?
   a. The water flosser was 29% more effective at removing plaque than string floss.
   b. The water flosser removed 82% of approximal plaque compared to 63% for string floss.
   c. Teeth water flossed for 3 seconds at medium pressure had 99.9% plaque removal.
   d. All statements are true.

4. People who added water flossing to power tooth brushing got better results in reducing:
   a. Stain
   b. Food debris
   c. Bleeding and gingivitis
   d. Halitosis

5. To what depth have researchers found the water flosser reduces pathogenic bacteria?
   a. 4 mm
   b. 6 mm
   c. 8 mm
   d. 12 mm

6. How much more plaque did the water flosser remove in orthodontic patients compared to string floss?
   a) 3.76 times as much
   b) 4.25 times as much
   c) 6.15 times as much
   d) 7.68 times as much

7. Which product has been implicated as a possible risk factor for peri-implantitis?
   a. Power toothbrushes
   b. Water flossers
   c. Traditional dental floss
   d. Mouthwash

8. When used with implants, the water flosser was how much more effective than string floss at reducing bleeding?
   a. 8 times more
   b. 6 times more
   c. 4 times more
   d. 2 times more

9. Water flossing for 30 days post-SRP has been shown to be as effective as what other regime?
   a. SRP plus regular dental flossing
   b. SRP plus power tooth brushing only
   c. SRP plus the local delivery of an antibiotic agent
   d. SRP plus systemic antibiotics

10. Which statement is true about dental floss?
    a. Studies prove it is the best tool for interproximal plaque removal.
    b. Studies prove it reduces interproximal caries.
    c. Studies prove it is the best device for reducing gingivitis.
    d. There is little to no evidence supporting the superiority of string floss over other devices.

11. How many published studies have been conducted on the water flosser?
    a. Over 100
    b. Over 70
    c. Less than 50
    d. Less than 35

12. Regarding the safety of the Water Flosser, which statement is true?
    a. The water flosser does not injure the soft tissue of the epithelium.
    b. The water flosser does not force bacteria into the pocket.
    c. The bacteremia produced by the water flosser is similar to brushing and flossing.
    d. All of the above.

13. Which statement is true regarding the use of mouthwash in a water flosser?
    a. Most types of mouthwashes can be used in the water flosser.
    b. The water flosser should be flushed with water after using mouthwash.
    c. Dilute chlorhexidine and an essential oil mouth rinse have been tested in a water flosser.
    d. All of the above.

14. How many different types of tips are available for the Water Flosser?
    a. 2
    b. 4
    c. 5
    d. 6

15. Which statement is true when using a Water Flosser?
    a. Do not start the flow of water until the tip is in the mouth.
    b. Bend from waist over the sink and avoid looking in the mirror.
    c. Use warm or room temperature water.
    d. All of the above.
